1 Introduction

Given the opportunity to review the **DefiDollar** smart contract source code, we in the report outline our systematic approach to evaluate potential security issues in the smart contract implementation, expose possible semantic inconsistencies between smart contract code and design document, and provide additional suggestions or recommendations for improvement. Our results show that the given version of smart contract can be further improved due to the presence of several issues. This document outlines our audit results.

1.1 About DefiDollar

DefiDollar (DUSD) is an index of stable coins that uses DeFi primitives to stay near the dollar mark more robustly than each individual stable coin. The vision behind DUSD is to provide an avenue for diversifying users' crypto-dollars positions, and to dampen the potentially disastrous effects of a particular stable coin such as Tether failing (partially or completely) from its peg.

The basic information of DefiDollar is as follows:

Item Description

Issuer DefiDollar

Website https://www.defidollar.xyz/

Type Ethereum Smart Contract

Platform Solidity

Audit Method Whitebox

Latest Audit Report August 25, 2020

Table 1.1: Basic Information of DefiDollar

In the following, we show the repository of the reviewed code used in this audit. We need to point out that DefiDollar assumes a trusted oracle with timely market price feeds and the oracle itself is not part of this audit. This is the commit ID the audit is based on:

• https://github.com/defidollar/defidollar-core (77dcbab)

And this is the commit ID after all fixes for the issues found in the audit have been checked in:

• https://github.com/defidollar/defidollar-core (185b4dd)

1.2 About PeckShield

PeckShield Inc. [18] is a leading blockchain security company with the goal of elevating the security, privacy, and usability of current blockchain ecosystems by offering top-notch, industry-leading services and products (including the service of smart contract auditing). We are reachable at Telegram (https://t.me/peckshield), Twitter (http://twitter.com/peckshield), or Email (contact@peckshield.com).

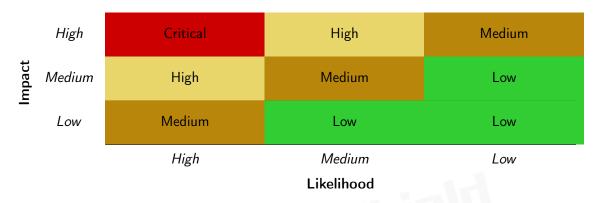

Table 1.2: Vulnerability Severity Classification

1.3 Methodology

To standardize the evaluation, we define the following terminology based on the OWASP Risk Rating Methodology [13]:

- <u>Likelihood</u> represents how likely a particular vulnerability is to be uncovered and exploited in the wild;
- Impact measures the technical loss and business damage of a successful attack;
- Severity demonstrates the overall criticality of the risk.

Likelihood and impact are categorized into three ratings: *H*, *M* and *L*, i.e., *high*, *medium* and *low* respectively. Severity is determined by likelihood and impact and can be classified into four categories accordingly, i.e., *Critical*, *High*, *Medium*, *Low* shown in Table 1.2.

To evaluate the risk, we go through a list of check items and each would be labeled with a severity category. For one check item, if our tool or analysis does not identify any issue, the

contract is considered safe regarding the check item. For any discovered issue, we might further deploy contracts on our private testnet and run tests to confirm the findings. If necessary, we would additionally build a PoC to demonstrate the possibility of exploitation. The concrete list of check items is shown in Table 1.3.

In particular, we perform the audit according to the following procedure:

- <u>Basic Coding Bugs</u>: We first statically analyze given smart contracts with our proprietary static code analyzer for known coding bugs, and then manually verify (reject or confirm) all the issues found by our tool.
- <u>Semantic Consistency Checks</u>: We then manually check the logic of implemented smart contracts and compare with the description in the white paper.
- Advanced DeFi Scrutiny: We further review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.
- Additional Recommendations: We also provide additional suggestions regarding the coding and development of smart contracts from the perspective of proven programming practices.

To better describe each issue we identified, we categorize the findings with Common Weakness Enumeration (CWE-699) [12], which is a community-developed list of software weakness types to better delineate and organize weaknesses around concepts frequently encountered in software development. Though some categories used in CWE-699 may not be relevant in smart contracts, we use the CWE categories in Table 1.4 to classify our findings.

1.4 Disclaimer

Note that this audit does not give any warranties on finding all possible security issues of the given smart contract(s), i.e., the evaluation result does not guarantee the nonexistence of any further findings of security issues. As one audit-based assessment cannot be considered comprehensive, we always recommend proceeding with several independent audits and a public bug bounty program to ensure the security of smart contract(s). Last but not least, this security audit should not be used as an investment advice.

Table 1.4: Common Weakness Enumeration (CWE) Classifications Used in This Audit

Category	Summary
Configuration	Weaknesses in this category are typically introduced during
	the configuration of the software.
Data Processing Issues	Weaknesses in this category are typically found in functional-
	ity that processes data.
Numeric Errors	Weaknesses in this category are related to improper calcula-
	tion or conversion of numbers.
Security Features	Weaknesses in this category are concerned with topics like
	authentication, access control, confidentiality, cryptography,
	and privilege management. (Software security is not security
	software.)
Time and State	Weaknesses in this category are related to the improper man-
	agement of time and state in an environment that supports
	simultaneous or near-simultaneous computation by multiple
Forman Canadiai ana	systems, processes, or threads.
Error Conditions,	Weaknesses in this category include weaknesses that occur if
Return Values, Status Codes	a function does not generate the correct return/status code, or if the application does not handle all possible return/status
Status Codes	codes that could be generated by a function.
Resource Management	Weaknesses in this category are related to improper manage-
Nesource Management	ment of system resources.
Behavioral Issues	Weaknesses in this category are related to unexpected behav-
Deliavioral issues	iors from code that an application uses.
Business Logics	Weaknesses in this category identify some of the underlying
Dusiness Togics	problems that commonly allow attackers to manipulate the
	business logic of an application. Errors in business logic can
	be devastating to an entire application.
Initialization and Cleanup	Weaknesses in this category occur in behaviors that are used
	for initialization and breakdown.
Arguments and Parameters	Weaknesses in this category are related to improper use of
	arguments or parameters within function calls.
Expression Issues	Weaknesses in this category are related to incorrectly written
	expressions within code.
Coding Practices	Weaknesses in this category are related to coding practices
	that are deemed unsafe and increase the chances that an ex-
	ploitable vulnerability will be present in the application. They
	may not directly introduce a vulnerability, but indicate the
	product has not been carefully developed or maintained.

2 | Findings

2.1 Summary

Here is a summary of our findings after analyzing the DefiDollar implementation. During the first phase of our audit, we studied the smart contract source code and ran our in-house static code analyzer through the codebase. The purpose here is to statically identify known coding bugs, and then manually verify (reject or confirm) issues reported by our tool. We further manually review business logics, examine system operations, and place DeFi-related aspects under scrutiny to uncover possible pitfalls and/or bugs.

Severity	# of Findings	
Critical	0	
High	3	
Medium	4	
Low	2	
Informational	2	
Total	11	

We have so far identified a list of potential issues: some of them involve subtle corner cases that might not be previously thought of, while others refer to unusual interactions among multiple contracts. For each uncovered issue, we have therefore developed test cases for reasoning, reproduction, and/or verification. After further analysis and internal discussion, we determined a few issues of varying severities need to be brought up and paid more attention to, which are categorized in the above table. More information can be found in the next subsection, and the detailed discussions of each of them are in Section 3.

2.2 Key Findings

Overall, these smart contracts are well-designed and engineered, though the implementation can be improved by resolving the identified issues (shown in Table 2.1), including 3 high-severity vulnerabilities, 4 medium-severity vulnerabilities, 2 low-severity vulnerabilities, and 2 informational recommendations.

Table 2.1: Key Audit Findings

ID	Severity	Title	Category	Status

3 Detailed Results

3.1 Incompatibility With Deflationary Tokens

• ID: PVE-001

Severity: MediumLikelihood: Low

• Impact: High

• Target: CurveSusdPeak

• Category: Time and State [8]

• CWE subcategory: CWE-362 [3]

Description

The CurveSusdPeak contract or peak is designed to work with a target Curve pool and exposes important interfaces to mint/redeem the stable coin index, i.e., DUSD. A user may deposit certain amount of supported SystemCoins or CurvePoolTokens into it to mint DUSDs. Later on, the same user can redeem her DUSDs to get the SystemCoins or CurvePoolTokens back. For the above two operations, i.e., mint and redeem, CurveSusdPeak provides low-level routines to transfer assets into or out of the peak (see the code snippet below). These asset-transferring routines work as expected with standard ERC20 tokens: namely the peak's internal asset balances are always consistent with actual token balances maintained in individual ERC20 token contract.

```
50
51
        * @dev Mint DUSD
52
        * @param inAmounts Exact inAmounts in the same order as required by the curve pool
53
        * @param minDusdAmount Minimum DUSD to mint, used for capping slippage
54
55
        function mint(
56
            uint[] calldata inAmounts,
57
            uint minDusdAmount
58
59
            returns (uint dusdAmount)
60
61
            address[N COINS] memory coins = underlyingCoins;
62
            uint[N COINS] memory pool sizes;
64
            for (uint i = 0; i < N COINS; i++) {
```

```
65
                pool sizes[i] = curve.balances(i);
66
                if (inAmounts[i] = 0) {
67
                    continue;
68
69
                IERC20(coins[i]).safeTransferFrom(msg.sender, address(this), inAmounts[i]);
70
            }
72
            LPShareInfo memory info;
73
            info.old lp amount = curveToken.balanceOf(address(this));
74
            info.old lp supply = curveToken.totalSupply();
76
            curveDeposit.add liquidity(inAmounts, 0);
78
            info.new lp amount = curveToken.balanceOf(address(this));
79
            info.new_lp_supply = curveToken.totalSupply();
81
            uint[] memory delta = new uint[](N COINS);
82
            for (uint i = 0; i < N_COINS; i++) {
83
                delta[i] = calcDepositDelta(info, pool sizes[i], inAmounts[i]);
84
            }
85
            return core.mint(delta, minDusdAmount, msg.sender);
86

for (uint i = 0; i < N_COINS; i++) {
    IERC20(coins[i]).safeTransfer(msg.sender, outAmounts[i]);
    delta[i] = _calcWithdrawDelta(info, pool_sizes[i], outAmounts[i]);
}
return core.redeem(delta, maxDusdAmount, msg.sender);
}</pre>
```

Listing 3.2: peaks/curve/CurveSusdPeak.sol

However, there exist other ERC20 tokens that may make certain customization to their ERC20 contracts. One type of these tokens is deflationary tokens that charge certain fee for every transfer or transferFrom. As a result, this may not meet the assumption behind these low-level asset-transferring routines. In other words, the above operations, such as mint and redeem, may introduce unexpected balance inconsistencies when comparing internal asset records with external ERC20 token contracts. Apparently, these balance inconsistencies are damaging to accurate and precise portfolio management of CurveSusdPeak and affects protocol-wide operation and maintenance.

One mitigation is to measure the asset change right before and after the asset-transferring routines. In other words, instead of bluntly assuming the amount parameter in transfer or transferFrom will always result in full transfer, we need to ensure the increased or decreased amount in the pool before and after the transfer or transferFrom is expected and aligned well with our operation. Though these additional checks cost additional gas usage, we consider they are necessary to deal with deflationary tokens or other customized ones if their support is deemed necessary.

Another mitigation is to regulate the set of ERC20 tokens that are permitted into DefiDollar for indexing. However, certain existing stable coins may exhibit control switches that can be dynamically exercised to convert into deflationary, which is out of DefiDollar's control.

Recommendation Apply necessary mitigation mechanisms to regulate non-compliant or unnecessarily-extended ERC20 tokens.

3.2 Possible Use of Outdated Price Feeds

• ID: PVE-002

• Severity: High

• Likelihood: Medium

• Impact: High

Target: UpgradableProxy

• Category: Business Logics [10]

• CWE subcategory: CWE-841 [7]

Description

Throughout the entire DefiDollar system, the Core contract performs the actual mint/redeem operations, pulls latest oracle feeds, and distributes protocol income to stakers. All these operations rely

on latest price feeds for precise measurement and calculation of system-wide assets or totalAssets (that is needed to calculate the actual amount during mint or redeem for example). We notice that the contract exhibits a public function named syncSystem() to allow anyone to pull latest oracle feeds. Specifically, syncSystem() calls _updateFeed() to get the latest prices of supported systemCoins (line 190).

```
182
183
         * Onotice Pull prices from the oracle and update system stats
184
         * @dev Anyone can call this
185
         */
186
         function syncSystem()
187
             external
             checkAndNotifyDeficit
188
189
190
             updateFeed();
191
             totalAssets = totalSystemAssets();
192
```

Listing 3.3: Core. sol

Though all these operations rely on latest price feeds, many of them do not always retrieve the latest price feeds. As an example, the mint operation may not get real-time prices from oracle (see the code snippets below at lines 116 122): the calculation of asset difference is performed with a cached price feeds. Notice that the use of outdated prices likely lead to inaccurate measurement of system-wide assets. Other affected operations include redeem(), rewardDistributionCheckpoint() and lastPeriodIncome(). We consider the freshness of these price feeds critical even though their guarantee may introduce additional gas cost.

```
94
 95
         * @notice Mint DUSD
 96
         * @dev Only whitelisted peaks can call this function
         * @param delta Delta of system coins added to the system through a peak
 97
 98
         * @param minDusdAmount Min DUSD amount to mint. Used to cap slippage
 99
         * @param account Account to mint DUSD to
100
         * @return dusdAmount DUSD amount actually minted

102
         function mint(
103
             uint[] calldata delta,
104
             uint minDusdAmount,
105
             address account
106
             external
107
             {\tt checkAndNotifyDeficit}
108
             returns (uint dusdAmount)
109
110
             Peak memory peak = peaks [msg.sender];
111
             require (
                 peak.state == PeakState.Active,
112
113
                 "Peak is inactive"
114
```

```
115
             uint usdDelta;
116
             SystemCoin[] memory coins = systemCoins;
117
             for (uint i = 0; i < peak.systemCoinIds.length; i++) {</pre>
                 SystemCoin memory coin = coins[peak.systemCoinIds[i]];
118
119
                 usdDelta = usdDelta.add(
120
                     delta[i]. mul(coin.price). div(coin.precision)
121
122
             }
123
             dusdAmount = usdToDusd(usdDelta);
124
             require(dusdAmount >= minDusdAmount, "They see you slippin");
125
             dusd.mint(account, dusdAmount);
126
             totalAssets = totalAssets.add(usdDelta);
127
             emit Mint(account, dusdAmount);
128
```

Listing 3.4: Core.sol

Recommendation Ensure the freshness of price feeds. To mitigate possible gas cost, an alternative is to implement the poke mechanism in the oracle such that it dynamically notifies the arrival of a new price feed. With that, there is no need to always invoke gas-heavy syncSystem() routine before the calculation of totalAssets.

3.3 Improved Sanity Checks in whitelistTokens()

- ID: PVE-003
- Severity: Low
- Likelihood: Low
- Impact: LowTarget: Core

- Category: Error Conditions, Return Values, Status Codes [11]
- CWE subcategory: CWE-391 [4]

Description

In the Core contract, the whitelistTokens() function allows the owner to set up or append the supported systemCoins. Notice that this function has three arguments, i.e., tokens, decimals, and initialPrices, and they are all dynamic arrays. It is necessary to ensure that they have the same length. Moreover, it is also needed to ensure there is no duplicate token in the provided argument and each indicates a new new token for systemCoins inclusion.

```
/**

282 /**

283 * @notice Whitelist new tokens supported by the peaks.

284 * These are vanilla coins like DAI, USDC, USDT etc.

285 * @dev onlyOwner ACL is provided by the whitelistToken call

286 * @param tokens Token addresses to whitelist

287 * @param decimals Token Precision

288 * @param initialPrices Intialize prices akin to retieving from an oracle
```

```
289
290
         function whitelistTokens (
291
             address[] calldata tokens,
292
             uint[] calldata decimals,
293
             uint[] calldata initialPrices
294
             external
295
             onlyOwner
296
         {
297
             for (uint i = 0; i < tokens.length; i++) {
                 whitelistToken(tokens[i], decimals[i], initialPrices[i]);
298
299
300
```

Listing 3.5: Core.sol

Recommendation Add necessary sanity checks to the whitelistTokens() routine. It is also suggested to ensure the provided decimals no larger than 18 - a restriction inherently assumed by the Curve protocol.

3.4 Simplified Execution Logic in mint()

• ID: PVE-004

• Severity: Infomational

• Likelihood: N/A

Impact: N/ATarget: Core

 Category: Error Conditions, Return Values, Status Codes [11]

• CWE subcategory: CWE-391 [4]

Description

The whitelisted peaks (e.g., CurveSusdPeak) can interact with the Core contract to mint the stable coin index, i.e., DUSD. The mint can be slightly optimized to speed up the internal loop when the condition delta[i] == 0 is satisfied. This brings a simplified logic with slightly improved performance benefit.

```
94
95
         * @notice Mint DUSD
96
         * @dev Only whitelisted peaks can call this function
97
         * @param delta Delta of system coins added to the system through a peak
98
         * @param minDusdAmount Min DUSD amount to mint. Used to cap slippage
99
         * @param account Account to mint DUSD to
100
         * @return dusdAmount DUSD amount actually minted
101
102
         function mint (
103
             uint[] calldata delta,
104
             uint minDusdAmount,
105
             address account
106
             external
107
             checkAndNotifyDeficit
108
             returns (uint dusdAmount)
109
110
             Peak memory peak = peaks [msg.sender];
111
             require(
```

```
peak.state == PeakState.Active,
112
113
                 "Peak is inactive"
114
             );
115
             uint usdDelta;
116
             SystemCoin[] memory coins = systemCoins;
117
             for (uint i = 0; i < peak.systemCoinIds.length; <math>i++) {
118
                 SystemCoin memory coin = coins[peak.systemCoinIds[i]];
119
                 usdDelta = usdDelta.add(
120
                     delta[i]. mul(coin.price). div(coin.precision)
121
122
             }
123
             dusdAmount = usdToDusd(usdDelta);
124
             require(dusdAmount >= minDusdAmount, "They see you slippin");
125
             dusd.mint(account, dusdAmount);
126
             totalAssets = totalAssets.add(usdDelta);
127
             emit Mint(account, dusdAmount);
128
```

Listing 3.7: Core. sol

Recommendation Simplify the above loop logic by checking delta[i] == 0.

```

107
             {\tt checkAndNotifyDeficit}
108
             returns (uint dusdAmount)
109
110
             Peak memory peak = peaks [msg.sender];
111
             require (
112
                 peak.state == PeakState.Active,
113
                 "Peak is inactive"
114
             );
115
             uint usdDelta;
116
             SystemCoin[] memory coins = systemCoins;
117
             for (uint i = 0; i < peak.systemCoinIds.length; <math>i++) {
118
                 if (delta[i] == 0) continue;
119
                 SystemCoin memory coin = coins[peak.systemCoinIds[i]];
120
                 usdDelta = usdDelta.add(
121
                      delta[i]. mul(coin.price). div(coin.precision)
122
                 );
123
             }
124
             dusdAmount = usdToDusd(usdDelta);
```

```
require(dusdAmount >= minDusdAmount, "They see you slippin");
dusd.mint(account, dusdAmount);
totalAssets = totalAssets.add(usdDelta);
emit Mint(account, dusdAmount);
}
```

Listing 3.8: Core.sol

3.5 Possible Unaccounted Staking Income

• ID: PVE-005

• Severity: High

Likelihood: Medium

• Impact: High

• Target: StakeLPToken

• Category: Business Logics [10]

• CWE subcategory: CWE-841 [7]

Description

Staking provided the last line of assurance in ensuring the stable coin index DUSD does not deviate wildly from the intended peg. For that, staking users are rewarded by potential incomes from the integrated peaks. The staking logic is implemented in the StakelPToken contract and one important functionality is to update protocol income from surrounding peaks.

The logic of updating protocol income is implemented in updateProtocolIncome(). Within the function, there is a critical variable named rewardPerTokenStored. This variable keeps track of the average reward for each staked DUSD token. We note that the variable is only updated via the updateProtocolIncome() function: It first calculates the last-period income and then updates rewardPerTokenStored.

```
function updateProtocolIncome() public {
    uint income = core.rewardDistributionCheckpoint();
    rewardPerTokenStored = rewardPerToken(income);
}
```

Listing 3.9: StakeLPToken.sol

The last-period income is calculated through an exported interface rewardDistributionCheckpoint () from the Core contract. We notice that it is exported, and is available for anyone to call. Unfortunately, if it is called not by the StakeLPToken contract, the last-period income becomes unaccounted to update the variable rewardPerTokenStored, leading to unexpected staking loss for all staking users!

```
194 function reward Distribution Checkpoint ()
195 external
196 check And Notify Deficit
197 returns ( uint )
```

```
198
199
             uint supply = dusd.totalSupply();
             totalAssets = totalSystemAssets();
200
201
             uint unclaimedRewards;
202
             if (totalRewards > claimedRewards) {
203
                  unclaimed Rewards = total Rewards.sub (claimed Rewards);\\
204
             }
205
             uint totalAssets = totalAssets.sub(unclaimedRewards);
206
             uint periodIncome;
207
             if ( totalAssets > supply) {
208
                  {\sf periodIncome} \ = \ \_{\sf totalAssets.sub(supply)};
209
                  totalRewards = totalRewards.add(periodIncome);
210
211
             return periodIncome;
212
```

Listing 3.10: Core.sol

Recommendation Ensure rewardDistributionCheckpoint() in the Core contract can only be invoked by StakeLPToken.

```
194
         function rewardDistributionCheckpoint()
195
             external
196
             onlyStakeLPToken
197
             {\tt checkAndNotifyDeficit}
198
             returns(uint)
199
200
             uint supply = dusd.totalSupply();
201
             totalAssets = totalSystemAssets();
202
             uint unclaimedRewards;
203
             if (totalRewards > claimedRewards) {
204
                 unclaimedRewards = totalRewards.sub(claimedRewards);
205
206
             uint _totalAssets = totalAssets.sub(unclaimedRewards);
207
             uint periodIncome;
208
             if ( totalAssets > supply) {
                 periodIncome = _totalAssets.sub(supply);
209
                 totalRewards = totalRewards.add(periodIncome);
210
211
212
             return periodIncome;
213
```

Listing 3.11: Core. sol (revised)

3.6 Locked Non-SystemCoins-Assets From Yield-Farming

• ID: PVE-006

Severity: MediumLikelihood: MediumImpact: Medium

• Target: StakeLPToken

Category: Business Logics [10]CWE subcategory: CWE-841 [7]

Description

By design, the peak refers to a yield generating protocol through which certain yields are expected after supported systemCoins are deposited. Using CurveSusdPeak as example, the contract supports a number of systemCoins, such as DAI, USDT, USDC, TUSD, and sUSD. Any user can deposit the above assets and then expect to receive certain rewards.

DefiDollar supports staking to provide the opportunity for staking users to receive all the underlying yield income while taking the risking of ensuring DUSD's peg. We notice that yield-farming may lead to gaining additional tokens that may not necessarily be part of supported SystemCoins, such as CRV or COMP.

From the currently implemented logic, these rewarded yields are locked in peaks, and stakers do not get their shares on these non-systemCoins yields. The discussion with the DefiDollar team indicates that the UpgradableProxy-based architecture allows for flexible new logic contract to be introduced and the built-in execute() function in the UpgradableProxy contract guarantees the purpose. However, this built-in function is considered omnipotent and could undermine the confidence on the logic implemented in DefiDollar, an issue we will further elaborate in Section ??.

Listing 3.12: UpgradableProxy.sol

Recommendation Add necessary helper routines to collect possible yield farming rewards. The distribution of these rewards can be achieved either on-chain or off-chain.

3.7 Possible Front-Running in syncSystem()

• ID: PVE-007

Severity: MediumLikelihood: MediumImpact: Medium

• Target: CurveSusdPeak

Category: Time and State [8]CWE subcategory: CWE-362 [3]

Description

In the Core contract, the syncSystem() function is responsible for updating the latest price feeds from the oracle. The price feeds ensure the accurate measurement and calculation of system-wide assets, i.e., totalAssets. This function is designed to be callable by anyone.

The market fluctuations likely introduce dynamics on the current prices of various systemCoins and accordingly bring economic implications for staking users. In addition, as mentioned earlier in Section 3.2, multiple functions in the Core contract do not use the latest price feeds and are thus susceptible to front-running by a malicious party. In particular, if a recent price update transaction, if submitted but not confirmed/mined yet, likely devalues the state into deficit, front-running can be launched to avoid upcoming staking loss due to the downward price update. In this case, the eventual staking loss, if any, may be inflicted on other innocent staking users.

Recommendation As suggested in Section 3.2, ensure the freshness of price feeds in the measurement and calculation of system-wide assets. And apply common wisdoms in known mitigation schemes, including various restrictions on the slippage limits (already used), allowed gas price ranges, and expiration times etc.

3.8 Code Optimization in getReward()

• ID: PVE-008

• Severity: Informational

Likelihood: N/AImpact: N/A

• Target: StakeLPToken

Category: Coding Practices [9]CWE subcategory: CWE-1041 [2]

Description

In the StakeLPToken contract, the getReward() routine is intended to obtain the calling user's staking rewards. The logic is rather straightforward in calculating possible reward, which, if not zero, is then allocated to the calling (staking) user.

Our examination shows that the current implementation logic can be further optimized. In particular, the getReward() routine has a modifier, i.e., updateReward(msg.sender), which timely updates the calling user's (earned) rewards in rewards[msg.sender] (line 94).

```
function getReward() public updateReward(msg.sender) {
    uint reward = earned(msg.sender);
    if (reward > 0) {
        rewards[msg.sender] = 0;
        core.mintReward(msg.sender, reward);
        emit RewardPaid(msg.sender, reward);
}
```

Listing 3.13: StakeLPToken.sol

Having the modifier updateReward(), there is no need to recalculate the earned reward for the caller msg.sender. In other words, we can simply re-use the calculated rewards[msg.sender] and assign it to the reward variable (line 95).

```
modifier updateReward(address account) {
    updateProtocolIncome();

if (account != address(0)) {
    rewards[account] = _earned(rewardPerTokenStored, account);
    userRewardPerTokenPaid[account] = rewardPerTokenStored;

}

_;

69
}
```

Listing 3.14: StakeLPToken.sol

Recommendation Avoid the duplicated calculation of the caller's reward in getReward(), which also leads to additional gas cost reduction.

```
function getReward() public updateReward(msg.sender) {
    uint reward = rewards[msg.sender];
    if (reward > 0) {
        rewards[msg.sender] = 0;
        core.mintReward(msg.sender, reward);
    emit RewardPaid(msg.sender, reward);
}
```

Listing 3.15: StakeLPToken.sol

3.9 Redemption Fee Miscalculation in dusdToUsd()

• ID: PVE-009

• Severity: Medium

Likelihood: Medium

• Impact: Medium

• Target: Core

• Category: Business Logics [10]

• CWE subcategory: CWE-837 [6]

Description

The redemption of the stable coin index DUSD requires accurate conversion from the redemption DUSD amount to the corresponding amount of dollars in USD. This conversion supports the collection of protocol-wide redemption fee that is specified in the system parameter redeemFee in basis points. Specifically, if there is the dollar amount usd for redemption, the final dollar amount the user can receive should be calculated as: usd.mul(redeemFee).div(10000), not usd.mul(10000).div(redeemFee).

However, our analysis shows the redemption fee is miscalculated in the wrong direction. Instead of charging the user for the redemption fee, the user is freely given the redemption fee as bonus! If exploited, a malicious actor can continuously call mint and then redeem to receive the "bonus" of the redemption fee until all assets hold in DefiDollar are eventually drained.

```
227
         function dusdToUsd(uint dusd, bool fee)
228
             public
229
             view
230
             returns(uint usd)
231
232
             // system is healthy. Pegged at $1
233
             if (!inDeficit) {
234
                 usd = dusd;
235
             } else {
236
             // system is in deficit, see if staked funds can make up for it
                 uint supply = dusd.totalSupply();
237
238
                 uint perceivedSupply = supply.sub(stakeLPToken.totalSupply());
239
                 // staked funds make up for the deficit
                 if (perceivedSupply <= totalAssets) {</pre>
240
241
                     usd = dusd;
242
                 } else {
243
                     usd = dusd.mul(totalAssets).div(perceivedSupply);
244
                 }
245
             if (fee) {
246
247
                 usd = usd.mul(10000).div(redeemFee);
248
249
             return usd;
250
```

Listing 3.16: Core. sol

Recommendation Properly calculate the due charge when DUSD is being redeemed.

```
227
         function dusdToUsd(uint dusd, bool fee)
228
              public
229
              view
230
              returns(uint usd)
231
232
             // system is healthy. Pegged at $1
              if (!inDeficit) {
233
                  usd = dusd;
234
235
             } else {
236
              // system is in deficit, see if staked funds can make up for it
                  uint supply = dusd.totalSupply();
237
238
                  uint perceivedSupply = supply.sub(stakeLPToken.totalSupply());
                  // staked funds make up for the deficit
239
240
                  if (perceivedSupply <= totalAssets) {</pre>
241
                      \mathsf{usd} \ = \ \_\mathsf{dusd} \, ;
242
                  } else {
243
                      usd = dusd.mul(totalAssets).div(perceivedSupply);
244
245
             }
              if (fee) {
246
247
                  usd = usd.mul(redeemFee).div(10000);
248
             }
249
              return usd;
250
```

Listing 3.17: Core.sol (revised)

3.10 Suggested Padding in Logic Contracts

ID: PVE-010Severity: LowLikelihood: Low

• Impact: Low

• Target: multiple contracts

• Category: Coding Practices [9]

• CWE subcategory: CWE-563 [5]

Description

As mentioned earlier, DefiDollar adopts a proxy-based approach to enable flexible updates of new versions of logic contracts. However, the proxy-based approach also comes with a few caveats. Since DefiDollar's upgradeability is achieved using inherited storage, one particular caveat is that this approach relies on making the logic contract to incorporate the storage structure required by the proxy. In other words, both the proxy (i.e., UpgradableProxy) and the logic contract inherit the same storage structure to ensure that both adhere to storing the necessary proxy state variables. In the case of multiple inheritance, the order in which parent contracts are declared on the child contracts also determines how their storages are laid out.

To ensure the consistency of inherited storage layouts while still maintaining necessary flexibility of extending logic contracts (including both parent and child contracts), it is suggested to add necessary padding at the end of local variables for each contract.

Using the Initializable contract as an example, current prototype does not reserve necessary padding space for future extensions.

```
pragma solidity 0.5.17;

contract Initializable {
   bool initialized = false;

modifier notInitialized() {
   require(!initialized, "already initialized");
   initialized = true;
   __;
}

initialized = true;
}
```

Listing 3.18: Initializable . sol

A suggested approach is to reserve padding storage (e.g., ____gap as shown in the code snippets below) at the end of contract. The reserved padding space can be used by future upgrades and its size depends on estimated need in the new versions of logic contracts. A typical size of 50 might suffice to meet most needs for relatively stable logic contracts.

```
1 pragma solidity 0.5.17;
```

```
3
   contract Initializable {
        bool initialized = false;
        modifier notInitialized() {
6
7
            require(!initialized , "already initialized");
8
            initialized = true;
9
10
       }
12
        // Reserved storage space to allow for layout changes in the future.
13
        uint256[50] private ___
14
```

Listing 3.19: Initializable . sol (revised)

Recommendation Reserve necessary storage space in logic contracts to allow for their future layout changes.

3.11 Inaccurate Delta Calculation During mint()/redeem()

• ID: PVE-011

Severity: High

• Likelihood: High

Impact: Medium

• Target: CurveSusdPeak

Category: Business Logics [10]

• CWE subcategory: CWE-837 [6]

Description

The minting of the stable coin index DUSD requires accurate calculation of Curve's pool balance difference due to the deposit. However, the calculation of Curve's balance is rather complicated as it is governed by the pricing curve behind Curve. Moreover, the trading fee as well as protocol-related administration fee (currently 0) also play a role in the balance calculation formula.

The formula is delicate and intrinsic to the Curve. It is our suggestion not to mock its execution for external balance calculation. Instead, take necessary steps to read the balances before and after the deposits and then calculate the balance difference (due to the deposit) according to the pricing curve.

Our analysis shows that current calculation in _calcDepositDelta() to derive the balance difference does not reflect the actual difference inside the Curve protocol. The simple addition between old_pool_size and amount (at line 194) does not take into consideration other factors, such as the protocol fee in Curve.

```
function _calcDepositDelta(
```

```
182
             LPShareInfo memory info,
183
             uint old pool size,
184
             uint amount
185
         )
186
             internal
187
             pure
188
             returns (uint /* delta */)
189
190
             uint old balance;
191
             if (info.old lp supply > 0) {
192
                 old balance = old pool size.mul(info.old lp amount).div(info.old lp supply);
193
194
             uint new balance = old pool size.add(amount).mul(info.new lp amount).div(info.
                 new lp supply);
195
             return new_balance.sub(old_balance);
196
```

Listing 3.20: CurveSusdPeak.sol

If we examine the logic in Curve, especially the relevant add_liquidity() routine, the new balance is calculated on self.balances[i] = new_balances[i] - fees[i] * _admin_fee / FEE_DENOMINATOR (line 260), where both fees and _admin_fee are configurable parameters during the pool initialization.

```
216 @public
217
    @nonreentrant('lock')
218
    def add liquidity (amounts: uint256 [N COINS], min mint amount: uint256):

286
        log.AddLiquidity(msg.sender, amounts, fees, D1, token_supply + mint_amount)
```

Listing 3.21: stableswap.vy

Note that the mint counterpart, i.e., redeem(), also shares the very same issue.

Recommendation Read the pool balances before and after the mint and redeem and correctly calculate their difference.

3.12 Other Suggestions

Due to the fact that compiler upgrades might bring unexpected compatibility or inter-version consistencies, it is always suggested to use fixed compiler versions whenever possible. As an example, we highly encourage to explicitly indicate the Solidity compiler version, e.g., pragma solidity 0.5.12; instead of pragma solidity ^0.5.12;.

In addition, there is a known compiler issue that in all 0.5.x solidity prior to Solidity 0.5.17. Specifically, a private function can be overridden in a derived contract by a private function of the same name and types. Fortunately, there is no overriding issue in this code, but we still recommend using Solidity 0.5.17 or above.

Moreover, we strongly suggest not to use experimental Solidity features or third-party unaudited libraries. If necessary, refactor current code base to only use stable features or trusted libraries.

Last but not least, it is always important to develop necessary risk-control mechanisms and make contingency plans, which may need to be exercised before the mainnet deployment. The risk-control mechanisms need to kick in at the very moment when the contracts are being deployed in mainnet.

4 Conclusion

In this audit, we thoroughly analyzed the DefiDollar design and implementation. The proposed system for stable coin index presents a unique innovation and we are really impressed by the overall design and implementation. The current code base is well organized and those identified issues are promptly confirmed and fixed.

Meanwhile, we need to emphasize that smart contracts as a whole are still in an early, but exciting stage of development. To improve this report, we greatly appreciate any constructive feedbacks or suggestions, on our methodology, audit findings, or potential gaps in scope/coverage.

5 Appendix

5.1 Basic Coding Bugs

5.1.1 Constructor Mismatch

• Description: Whether the contract name and its constructor are not identical to each other.

• Result: Not found

• Severity: Critical

5.1.2 Ownership Takeover

• Description: Whether the set owner function is not protected.

• Result: Not found

Severity: Critical

5.1.3 Redundant Fallback Function

• Description: Whether the contract has a redundant fallback function.

• Result: Not found

• Severity: Critical

5.1.4 Overflows & Underflows

• <u>Description</u>: Whether the contract has general overflow or underflow vulnerabilities [14, 15, 16, 17, 19].

• Result: Not found

• Severity: Critical

5.1.5 Reentrancy

• <u>Description</u>: Reentrancy [20] is an issue when code can call back into your contract and change state, such as withdrawing ETHs.

• Result: Not found

• Severity: Critical

5.1.6 Money-Giving Bug

• Description: Whether the contract returns funds to an arbitrary address.

• Result: Not found

• Severity: High

5.1.7 Blackhole

• <u>Description</u>: Whether the contract locks ETH indefinitely: merely in without out.

• Result: Not found

• Severity: High

5.1.8 Unauthorized Self-Destruct

• Description: Whether the contract can be killed by any arbitrary address.

• Result: Not found

• Severity: Medium

5.1.9 Revert DoS

• Description: Whether the contract is vulnerable to DoS attack because of unexpected revert.

• Result: Not found

• Severity: Medium

5.1.10 Unchecked External Call

• Description: Whether the contract has any external call without checking the return value.

• Result: Not found

• Severity: Medium

5.1.11 Gasless Send

• Description: Whether the contract is vulnerable to gasless send.

• Result: Not found

• Severity: Medium

5.1.12 Send Instead Of Transfer

• Description: Whether the contract uses send instead of transfer.

• Result: Not found

• Severity: Medium

5.1.13 Costly Loop

• <u>Description</u>: Whether the contract has any costly loop which may lead to Out-Of-Gas exception.

• Result: Not found

• Severity: Medium

5.1.14 (Unsafe) Use Of Untrusted Libraries

• Description: Whether the contract use any suspicious libraries.

• Result: Not found

• Severity: Medium

5.1.15 (Unsafe) Use Of Predictable Variables

• <u>Description</u>: Whether the contract contains any randomness variable, but its value can be predicated.

• Result: Not found

• Severity: Medium

5.1.16 Transaction Ordering Dependence

• Description: Whether the final state of the contract depends on the order of the transactions.

• Result: Not found

• Severity: Medium

5.1.17 Deprecated Uses

• <u>Description</u>: Whether the contract use the deprecated tx.origin to perform the authorization.

• Result: Not found

• Severity: Medium

5.2 Semantic Consistency Checks

• <u>Description</u>: Whether the semantic of the white paper is different from the implementation of the contract.

• Result: Not found

Severity: Critical

5.3 Additional Recommendations

5.3.1 Avoid Use of Variadic Byte Array

• <u>Description</u>: Use fixed-size byte array is better than that of byte[], as the latter is a waste of space.

• Result: Not found

• Severity: Low

5.3.2 Make Visibility Level Explicit

• Description: Assign explicit visibility specifiers for functions and state variables.

• Result: Not found

• Severity: Low

5.3.3 Make Type Inference Explicit

• <u>Description</u>: Do not use keyword var to specify the type, i.e., it asks the compiler to deduce the type, which is not safe especially in a loop.

• Result: Not found

Severity: Low

5.3.4 Adhere To Function Declaration Strictly

• <u>Description</u>: Solidity compiler (version 0.4.23) enforces strict ABI length checks for return data from calls() [1], which may break the the execution if the function implementation does NOT follow its declaration (e.g., no return in implementing transfer() of ERC20 tokens).

• Result: Not found

Severity: Low
